Chapter 1

Introduction

The Geophysical Fluids Modeling Framework (GAME) is a non-hydrostatic hexagonal C grid dynamical core with the possibility to advect a variable number of tracers. The term *dynamical core* typically refers to the simulation of a dry atmosphere. Everything else is then referred to as *physics*. Diffusive terms, including turbulence parameterizations, are sometimes understood to be part of the dynamical core and sometimes seen as part of the model's physics. The dry air is in this understanding a "carrier medium", whereas tracers, including water in different phases, are usually only passively advected. This thinking always leads to deep physical inconsistencies during later stages of model development, whose impact on forecast and climate simulation accuracy remains unknown.

Therefore, a new, capable framework for simulating geophysical fluids is necessary and, due to the advent of even more powerful computers, also realistic. The GAME can be seen as a dynamical core, but not in the traditional sense, instead rather in a modernized sense. Its aim is to simulate the dynamics of geophysical fluid flow accurately, and at the same time make it possible to couple the model to different tracers *consistently*, which means without violating fundamental physical constraints. Following a modular way of thinking, the actual quantifications of the tracer's source terms have been split off into the *atmo*tracers library [2], which is meant to evolve into a wide collection of source terms for atmospheric tracers, also including chemistry and parameterizations. For radiation, it is coupled to the RTE+RRTMGP (Radiative Transfer for Energetics + Rapid and Accurate Radiative Transfer Model for Geophysical Circulation Model Applications-Parallel) [8], [10] scheme, which follows a similar approach to radiation simulation as GAME follows to fluid simulation.

Chapter 2

Code structure

The code of the model resides in the directory `core/src`. Every subdirectory in there, including `core/src` itself, contains a file named `info` containing information on the purpose and contents of this specific directory.

Chapter 3

Grid generation

3.1 Fundamental grid quantities

The following quantities are sufficient to uniquely define the grid:

- the horizontal coordinates of the generating points
- the numbering of the generating points
- the numbering and orientation of the horizontal vectors
- the numbering of the dual cell mid points
- the numbering and orientation of the dual horizontal vectors

All other quantities, be it floating point numbers like grid box volumes or areas, or integer quantities like neighborhood relationships, can be implicitly derived. Consequently, one must firstly focus on the fundamental grid properties.

3.1.1 Creating a spherical geodesic grid

3.1.2 Numbering and orienting the vector points

3.1.3 Numbering and orienting the dual vector points

Until now, we have only operated with the six following arrays:

- `latitude_scalar, longitude_scalar`
- `from_index, to_index`
- `from_index_dual, to_index_dual`

3.2 Derived quantities

3.2.1 Horizontal coordinates of dual cell midpoints

3.2.2 Finding the neighboring vector points of a primal cell and their orientation

3.2.3 Finding the neighboring vector points of a dual cell and their orientation

3.3 Grid optimization

Hexagonal spherical grids need to be optimized for numerical modeling. Therefore, the Lloyd algorithm is used, which yields a *spherical centroidal Voronoi tessellation (SCVT)* after convergence [3]. [7] gives an overview of optimization alternatives and it seems to be that the SCVT is the most suitable for modeling. The procedure employed for executing the Lloyd algorithm is the one described in [6].

Figure 3.1: A subset of a regular horizontal hexagonal grid. The hexagonal grid (blue lines) and the triangular grid (red lines) form a pair of a primal-dual grid. In GAME, the hexagonal grid is the primal grid, while the triangular grid forms the dual one. In a triangular grid model it is the other way around. During the grid generation procedure we refer to the triangle edge points (hexagon centers) as the generating points or generators, for short.

Figure 3.2: A sample hexagon with a horizontal scalar index of 5381. The directions of the arrows indicate the directions of unit vectors at cell edges. The drawn orientations would lead to $\text{adjacent_vector_signs_h}[6 \cdot 5381 + 0] = 1$, $\text{adjacent_vector_signs_h}[6 \cdot 5381 + 1] = 1$, $\text{adjacent_vector_signs_h}[6 \cdot 5381 + 2] = 1$, $\text{adjacent_vector_signs_h}[6 \cdot 5381 + 3] = -1$, $\text{adjacent_vector_signs_h}[6 \cdot 5381 + 4] = 1$, $\text{adjacent_vector_signs_h}[6 \cdot 5381 + 5] = -1$.

3.4 Vertical grid structure

3.5 Scalability

The computation time of the most expensive for loops scale with N^2 , where N is the number of horizontal grid points. This means that doubling the horizontal resolution (four times as much horizontal grid points) leads to a 16 times longer computation time of the grid generator. This is similar to the model itself, where a doubling of the horizontal and vertical resolution and a halvening of the time step leads to 16 times longer integration times. Therefore, the largely implicit formulation of the grid generator poses no problem to its performance at higher resolutions.

3.5.1 Permutations of the grid points

Chapter 4

Orography generator

Chapter 5

Prognostic and diagnostic quantities

Chapter 6

Test generator

Chapter 7

Spatial operators

- Coriolis: [1] and [9] modified by [5]
- kinetic energy: [4]

Chapter 8

Time stepping

Runge-Kutta third order scheme (RK3). In the vertical, at every substep, implicit methods are used.

Chapter 9

Input and output

Chapter 10

Coupling to the radiation field

GAME employs the so-called RTE+RRTMGP (Radiative Transfer for Energetics + Rapid and Accurate Radiative Transfer Model for Geophysical Circulation Model Applications-Parallel) [8], [10] scheme. It is bound to the C code through the API RTE-RRTMGP-C [11].
